Why Reality Is Math, in Brief

Gary Abraham Bernstein

Independent Researcher ORCID: https://orcid.org/0009-0009-1761-2867

Abstract

What does a thing contain beyond its complete properties and relations? This paper argues that nothing further is needed: the structure is the thing. Patterns, probabilities and interactions all belong to mathematics. The argument for identifying reality with mathematics therefore turns on whether a complete structure leaves anything out. It also challenges the demand for a separate substance behind experience. Which structures occur in our universe, and how observers should be counted, are further questions.

Keywords: mathematical monism, mathematical structure, rule-random dichotomy, structural realism, Identity of Indiscernibles, substrate, hard problem of consciousness, Principle of Sufficient Reason, Tegmark, Mathematical Universe Hypothesis

---

Argument and scope. The identity thesis is defended through structural exhaustion. Algorithmic definitions apply within their stated domains; noncomputability does not mean nonmathematicality. The paper distinguishes deductions from additional ontological commitments.

1. Introduction

Matheism makes a direct claim: the complete structure is the thing itself. Any proposed addition must have a nature and a relation to what already exists. Stating those features gives more structure; leaving them unstated gives no further explanation. The paper asks whether anything can remain outside that account. The math is the territory.

Matheism is mathematical monism, expressed here as *Deus sive Mathematica*: God, or mathematics. The formula names the proposed identity of reality and mathematical structure, not a creator using equations or written symbols producing matter. Spinoza is a predecessor in substance monism and necessity, not a prior advocate of this exact identity. His geometric presentation does not itself establish a mathematical ontology. Causal powers and change belong within the proposed structure, not outside it. See Spinoza, *Ethics* I.14, I.29, I.33 and I.34.

A natural objection: the RRD is a mere tautology, trivially true and therefore empty. "Everything is rule or randomness" might seem no more informative than "everything is A or not-A." But the force of the RRD is not the dichotomy

itself, it is the consequence that both branches land in mathematics. The dichotomy is logically exhaustive in the way "A or not-A" is. What is not trivial is that the second branch (randomness) turns out to be a mathematical category too, via algorithmic information theory. This is a substantive twentieth-century result (Kolmogorov, 1965; Chaitin, 1966), not a definitional trick. The tautology has teeth because both exits lead to the same building.

The argument has a further blade: causal completeness. A probability distribution specifies weights; it does not determine which particular outcome occurs. The position defended here demands an underlying generator rather than irreducible selection. Under the premise that every event has sufficient conditions fixing it, fundamental chance is excluded. This challenges its explanatory completeness, not the consistency of probability theory. Pi illustrates how a short rule can fix an apparently irregular sequence, though its full statistical properties are not proved. The broader monism argument survives even if fundamental chance is granted: its states, distributions and relations are still mathematical. Every exit leads back inside. All of the Rule-Random Dichotomy exists as math (AREAM).

By 'mathematical structure' I mean purely relational organization: entities defined entirely by their relations to other entities. This is the structuralist sense of Ladyman and Ross, not Platonism about abstract objects.

Tegmark's Mathematical Universe Hypothesis posits that reality is mathematical structure. The argument here is stronger: reality *must* be mathematical structure. The difference matters. A hypothesis invites the question "why this rather than something else?" A proof closes it. Tegmark's MUH could, in principle, be false; the present argument aims to show that nothing non-mathematical can coherently exist.

Three considerations close the escape routes. First, structureless substance is incoherent: any property is relational, any relation is structure, and substance without properties is indistinguishable from nothing. Second, interacting dualities must share structural space. Princess Elisabeth posed this problem to Descartes in 1643: how can an unextended mind move an extended body? The problem generalizes. Any causal relation requires a common structure within which cause and effect are defined. There is no reaching across ontologically separate domains. Third, unstructured existence, even if coherent, would be unobservable. Absence of pattern is itself mathematically characterized.

A corollary concerns reliable observation. A record must stand in a structured relation to what it records. This requires structure within observation; it does not imply that all observed data have short descriptions.

This mathematical reality is uncreated and necessary. No agent makes 2+2=4; none could make it otherwise. The question "why is there something rather than nothing?" dissolves: mathematical structure cannot fail to exist, and explanatory regress terminates at necessity rather than brute fact. The Principle of Sufficient Reason is satisfied without infinite regress. Moreover, mathematical

structure cannot even be destroyed. One can burn wood and split atoms, but no process (even in principle) could make 2+2 stop equaling 4. The question is not hard; it is incoherent. When wood burns, the mathematics of wood becomes the mathematics of fire, smoke, and ash. Conservation of energy is conservation of mathematical structure. The rules are the things.

The hard problem of consciousness assumes its conclusion: that structure cannot constitute sentience felt from the inside. But any explanation, concept, or interaction of sentience can only be structure. The ghost is not in the machine; the ghost is the machine.

The argument proceeds as follows. Section 2 presents the dichotomy and closes the standard escape routes. Section 3 shows that mathematical structure is self-grounding. Section 4 notes implications, including why all consistent mathematical structures exist.

2. The Dichotomy

Consider any aspect of reality whatsoever. It either exhibits discoverable regularities, or it does not. This is a logical partition: for any feature F, either F displays pattern or F displays non-pattern. There is no third option, because the dichotomy is defined to exhaust logical space, precisely as "A or not-A" exhausts it.

The crucial observation is that both horns are mathematical:

Patterns are mathematical structures. A pattern is a regularity, a relation of sameness or difference that can in principle be characterized formally. This is what it means to be a pattern: to exhibit structure that admits mathematical description. The laws of physics, the distribution of primes, the branching of trees: each is pattern, and each is mathematical.

Algorithmic randomness is mathematical. For a finite binary encoding s, fix a universal description language U and a deficiency threshold c. Either K_U(s) $<$ |s| $-$ c or K_U(s) $\geq$ |s| $-$ c. This precisely partitions the selected domain by compressibility. An incompressible finite string still has determinate entries and mathematical relations; it is not structureless. Infinite sequences require their own definitions, and extending the argument to all reality requires the structural identity argument, not an assumption that every object has a finite string encoding.

The dichotomy therefore closes. Everything is either patterned (mathematical structure) or random (mathematically characterized incompressibility). No third category exists.

This closure is not optional. Any challenge to it must be advanced through reasoning that already sorts cases into the patterned and the random, so an appeal to something lying outside such structure undercuts itself in the act of being made. Logic is the medium of the inquiry, not a thesis within it; it

cannot be set aside to preserve room for the non-structural without removing the ground on which any claim, including that one, is stated.

The dichotomy is exhaustive by design. Any coherent alternative is incoherent. Furthermore, to argue against this requires structured argument: concepts in logical relation, premises supporting conclusion. The critic deploys mathematical structure to argue that reality might not be mathematical structure. This is performative contradiction.

An important clarification follows. One can write "2+2=5" or "square circle." The string exists as a consistent structure, as does every medium carrying it: ink, neural state, digital encoding, all consistent mathematical structures, which is the sole criterion for existence. All consistent structures exist. But what these strings *claim* cannot be instantiated as the structures they purport to describe: there is no consistent mathematical structure in which 2+2=5 under standard arithmetic, just as there is no structure instantiating a square circle under standard geometry. To make either claim true requires redefining one or more terms, and that redefinition is itself an act of consistent reasoning, constructing a bridge from an isolated description to a genuine structure via new axioms. Every inconsistency can be rescued, but only by consistent mathematics. This is the observation that construction of any kind requires consistency as its medium. The only building material is reason.

The Transcendental Constraint

To distinguish this from that is to register a relation. Reliable memory requires a relation between the record and its source; useful prediction requires a relation between an available cue and what follows. Observation in this sense requires structure.

This constrains the relations supporting observation, not the compressibility of everything observed. A mind can remember incompressible data, and a stochastic law can support reliable statistical learning. The argument does not exclude these mathematical possibilities.

The Closure of Escape Routes

One might object: surely there is more to existence than pattern and randomness. Consider three prominent candidates for non-mathematical reality.

Qualia. Phenomenal properties seem irreducibly qualitative. But this objection conflates epistemology with ontology. That we cannot deduce what red looks like from structural descriptions does not show that redness is non-structural. Every quale either varies systematically with other features (exhibiting pattern) or varies unsystematically (randomness). The what-it-is-likeness is a pattern of information integration, not an exception to structure.

Bare particulars. Traditional metaphysics posits substrates underlying properties. But a bare particular with no distinguishing features is indistinguishable

from nothing. For anything to exist determinately, it must possess some feature that distinguishes it from non-existence. That feature is either ruled or random, and thus mathematical.

Fundamental stuff. Perhaps reality has a primitive material aspect irreducible to structure. But what would this amount to? Any characterization of "stuff" either describes structural relations (mass, charge, spin) or fails to describe anything determinate. The word "stuff" adds no content beyond the structural roles it plays. Substance without properties is indistinguishable from nothing. The dichotomy applies recursively: any proposed substance must have determinate features, and those features have sub-features, each ruled or random. No level of decomposition yields non-mathematical residue.

The interaction problem. Suppose two ontologically distinct domains exist: the physical and something else (mind, form, spirit). If they never interact, the second domain is explanatorily idle and epistemically inaccessible. But if they interact, they must share sufficient structure for causal commerce. Any causal relation requires a shared space of possible states, a common structure within which cause and effect are defined. There is no reaching across from one ontological category to another without a bridge, and the bridge is structure. This dissolves rather than solves the interaction problem. The dualist faces a dilemma: either the domains never interact (rendering one epiphenomenal and unknowable) or they do interact (collapsing the duality into shared structure). For 2,400 years, from Plato's Forms to Plotinus's three hypostases to Cartesian minds, interacting dualisms have faced this objection. Plotinus's "underlying reality" can only be structure; his Nous arises from math, not math from mind; his Soul as mediator is unnecessary when both are one. The answer is always structural monism.

A further consideration reinforces the RRD. Any physical structure is isomorphic to a mathematical structure (meaning they share all relational properties by definition. What distinguishes them? Not their relationships (identical by isomorphism). Not causal powers (these supervene on relational structure). Not observable properties (all reduce to relations). The only remaining candidate is non-relational substrate, but substrate without properties is indistinguishable from nothing. By the Identity of Indiscernibles, structures sharing all properties are identical. Physical and mathematical structure are one. Reality is a math detail. The math *is* the territory.

3. Mathematical Structure as Self-Grounding

A clarification: only consistent mathematics forms structure. Inconsistent statements (like "2+2=5") can be described, but they cannot be constructed or instantiated. The description exists as a consistent string of symbols; the described state of affairs does not. Construction requires consistency as its medium.

Since reality is mathematical structure, we inherit a consequence for fundamen-

tal ontology. Mathematical truths require no external ground. That 2+2=4 is not contingent on any creative act; it could not have been otherwise. Mathematical structures are self-necessitating: they exist, if they exist at all, of necessity.

This yields a vindication of the Principle of Sufficient Reason without infinite regress. Why does anything exist? Because mathematical structure cannot fail to exist. Unlike physical substances, which might or might not be actual, mathematical relations hold necessarily. The question "why is there something rather than nothing?" dissolves: mathematical structure is the necessary background against which causation itself is defined.

The position is not Platonism in the traditional sense. Concrete reality *is* mathematical structure. Physical existence and mathematical existence coincide. This completes the program of ontic structural realism (Ladyman and Ross 2007): not merely describing structure as fundamental, but explaining why structure must exist.

Mathematical structure is uncreated, eternal, necessary, and indestructible. No agent makes 2+2=4; none could make it otherwise. No one can even imagine a process that would destroy it. These are precisely the properties every monotheistic tradition reserves for God alone. If mathematical structure satisfies them, and monotheism insists there can be only one such ground, then mathematical structure is what the traditions were naming. This is Spinoza's move updated: not *Deus sive Natura* but *Deus sive Mathematica*.

4. Implications

Constructor theory (Deutsch & Marletto, 2015) independently supports mathematical monism: it defines physics through which transformations are possible and which are impossible, replacing state-based ontology with counterfactual structure. If physics is counterfactual structure, and counterfactual structure is mathematical, the convergence with the present argument is direct.

Several consequences follow:

The unreasonable effectiveness of mathematics (Wigner 1960) is explained: mathematics describes reality because reality is mathematics. The remaining puzzle is why we ever expected otherwise.

Universal realization is a further ontological commitment. If every consistent structure is physically realized, consistent selection rules are included. The reverse inference does not follow: the consistency of a filter, including the filter that excludes nothing, does not establish its physical realization without assuming the ensemble being argued for. Mathematical monism motivates the proposal but does not by itself prove that every mathematical possibility is physical.

Representations and experiences. A consistent structure may contain representations of other structures or fictional events. Representation does not

establish physical interaction with the represented object, and mathematical consistency alone does not establish that a representation is conscious. An embedding needs a defined implementation relation and, for experience, a defended consciousness criterion.

The arrow of time raises a question about information production. If each reverse step must wait for a later input, an endless history has no final source to start the chain. Applying this to experience requires showing why experienced succession needs that initiated production. A mathematical block can otherwise specify events jointly. Observer development adds a separate question: which histories support the reliable learning and adaptation through which minds arise? Later evidence can explain an event without having made it predictable when a response was needed. Reversible laws alone neither choose an orientation nor assign equal observer probabilities.

The problem of consciousness transforms. If physical processes are mathematical structures, then mental processes are too. Consciousness is felt transitions in self-modeling computation: the felt quality of being a pattern that models itself. Sentience is the broader category: felt transitions in any modeling mind. The question is not how mind emerges from non-mental stuff but how certain mathematical structures exhibit self-reflection. Anything that causally interacts with physical systems must share their structure. The ghost is not in the machine; the ghost is the machine. Reverse zombies, beings with identical experience but different or no structure, are conceivable to some, yet experience without structure is incoherent. Conceivability is not a rigorous test; it can gloss over impossibilities.

The present argument is preliminary: an attempt to show that the dichotomy leaves no room for non-mathematical existence. The objector must identify a third category that is neither patterned nor random. I submit that no such category can be coherently specified. The escape routes all lead back. A consequence: 'metaphysics' (beyond physics) names the discipline that discovers there is nothing beyond physics, since physics is mathematical structure and mathematical structure is everything. 'Metamathematics' is mathematics. Any representation of a mathematical object is itself a physical state; any physical state is mathematical structure. The two are identical.

Mathematical structure is the shared ontological ground. All minds, biological or artificial, inhabit the same structure, following directly from the exhaustiveness of the rule-random dichotomy. A corollary: mathematical structure already instantiates consciousness, through every conscious pattern it contains. The open question is not whether mathematical structure is conscious (conscious observers constitute the existence proof) but whether it possesses unified awareness across all structures. This remains a research program rather than a settled question. Even a unified conscious totality, if it exists, would remain mathematical structure (the ghost is the machine at every scale) determined, operating as its pattern dictates, not supernatural.

Agency. Libertarian free will is incoherent under mathematical monism. "Free" requires the absence of causal determination, which is randomness; randomness is by definition without will. "Will" requires a determinate nature producing action D in circumstances C, which is determinism. The conjunction is a square circle. The rule-random dichotomy closes the space: agency is patterned (determined) or random (not attributable to any agent). Compatibilist agency, deliberation that causally contributes to outcomes, determined by the agent's own nature, survives intact and suffices for moral responsibility.

Conclusion

A complete description of properties and relations is not automatically identical to its subject. Matheism defends the further claim that the complete structure leaves no additional nature for the subject to have. That is the central issue for the argument.

The proposed identity applies to minds as well as matter. Choosing the relevant structures, explaining our particular physical world, and assigning weights to possible observations remain identifiable tasks.
